### ABSTRACT

The purpose of this study is to investigate how motor learning might help fourth-semester Physical Education students enhance their mental and physical balance. Emphasizing coordination, control, and balance-based tasks, 76 pupils took part in an eight-week organized motor learning program. Data were examined using paired sample t-tests employing a quantitative pretest-posttest methodology. The findings showed notable gains in mental as well as physical balance. Whereas the mental balance score improved from 58.20 to 70.55, the mean physical balance score rose from 62.45 to 75.80. The results were statistically significant— $p < 0.05$ . These results imply that motor learning improves not just neuromuscular coordination but also cognitive attention and emotional control. The study concludes that for Physical Education students, motor learning is a successful and all-encompassing approach to acquiring both physical and mental competencies. Integration of motor learning exercises into standard physical education courses is advised in order to promote well-rounded student development.

## INTRODUCTION

Particularly for physical education students, motor learning is a fundamental component in the acquisition of physical ability and cognitive coordination. Executing motor tasks with accuracy depends on coordination, so it affects general physical education performance. Improved educational results in sports and physical activity connect with higher degrees of motor coordination (Bozaxhiu et al., 2024). Programs, including motor cognitive coordination training, significantly improve gross motor abilities and working memory in pupils by combining physical exercise with cognitive tasks (Setiawan et al., 2020). In physical education, effective teaching strategies can improve student involvement and motor competency, therefore enhancing learning opportunities (Colella, 2016). Customizing events to fit personal demands will help to maximize motor learning results (Infante et al., 2023). Combining free inquiry with controlled learning might produce a more complete educational process. It covers the procedures connected to experience or practice that result in somewhat permanent changes in mobility capacity. In the framework of physical education, good motor

learning improves not only students' physical ability but also their psychological well-being and cognitive growth.

Whereas mental balance relates to psychological stability, including focus, self-regulation, and emotional control, physical balance is the body's capacity to maintain posture and stability during movement. The ocular, vestibular, and somatosensory systems together provide information about body position and movement that the central nervous system (CNS) processes in physical balance (Januário & Amaral, 2010). Adapting to changes in the surroundings and body posture, the neural system coordinates muscular activities to preserve posture (Nashner, 2009). Preventing falls depends on effective balance; this is especially important in aging populations when disabilities can cause significant health hazards (Kot & Nawrocka, 2016). Maintaining emotional stability and good decision-making requires self-regulation and attention, which define mental balance (Mancini et al., 2020). Although physical balance is sometimes stressed in talks of stability, general well-being depends much on mental equilibrium. The interaction of these two kinds of balance emphasizes the need for a comprehensive approach to stability and health since it implies that improving one may favorably affect the other. Physical education students are expected to have significant degrees of both physical coordination and mental resilience as future teachers and movement practitioners. Thus, maximizing the results of physical education programs depends on investigating the effects of motor learning on these two spheres.

Many studies have indicated that task-oriented movement exercises, coordination drills, and balance training—among other structured motor learning activities—can significantly increase neuromuscular control and lower mental tiredness. Furthermore, deliberate movement exercises foster concentration, confidence, and stress reduction—all of which are fundamental components of mental equilibrium. Further research on how these learning strategies may be purposefully included in physical education courses will help to maximize student development holistically. This paper attempts to investigate how motor learning might improve physical education students' mental and physical equilibrium. The study aims to provide an understanding of how important ideas and useful applications of motor learning enhance student performance, health, and educational achievement through their supporting mechanisms.

## **RESEARCH METHODOLOGY**

The function of motor learning in enhancing students' physical and mental equilibrium was investigated in this quantitative study employing a quasi-experimental design technique. One treatment group under a pretest-posttest group design made up the research plan. The eight-week trial was scheduled with three times a week of instruction. Coordination training, dynamic and static balance training, and challenging motor exercises demanding concentration and movement control comprised the motor learning program offered. Participants underwent a physical balance test employing the Balance Error Scoring System (BES) and a mental balance test administered via a validated concentration and emotional control scale both before and after therapy. With a total of 76 persons chosen purposefully depending on the fit of the inclusion criteria, the sample in this study were active students of the 4th semester Physical Education program at a public university. Students who enroll in motor practice courses and have no history of significant injuries or balance problems are among these

requirements. Using a paired sample t-test, the collected data were examined to find the variations in scores before and after therapy. Using the most recent SPSS version, statistical analysis was conducted with a significance level defined at  $p < 0.05$ .

## RESULTS

Following an eight-week motor learning program, the results of this study show notable increases in both physical and mental balance among fourth-semester physical education students. Pairing sample t-tests allowed the pretest and posttest scores of the subjects to be compared in the analysis. The statistical results are compiled here:

Table 1. Paired Sample t-test Results for Physical and Mental Balance

| Variable         | Mean (Pretest) | Mean (Posttest) | Mean Difference | t-value | Sig. (2-tailed) |
|------------------|----------------|-----------------|-----------------|---------|-----------------|
| Physical Balance | 62.45          | 75.80           | 13.35           | 9.874   | 0.000           |
| Mental Balance   | 58.20          | 70.55           | 12.35           | 8.612   | 0.000           |

Table 1 shows that following motor learning treatment, there was a notable average rise in both measures. Whereas mental balance rose from an average of 58.20 to 70.55, physical balance changed from an average of 62.45 to 75.80. With a 0.000 significance value for both variables— $p < 0.05$ —the increase is statistically significant. These findings show that motor learning significantly and favorably improves the physical and mental equilibrium of Physical Education students. A well-organized training program aimed at motor coordination and emotional control has proved successful in supporting the complete development of student performance.

This study shows that among physical education students, a systematic motor learning program can significantly improve both physical and mental balance. Particularly in physical education environments, the statistical results demonstrate notable increases in postural control and psychological stability, two vital elements of student achievement. The rise in physical balance implies that motor learning activities—such as coordination exercises, dynamic balancing tasks, and proprioceptive training—helped strengthen the neuromuscular system, enhanced body awareness, and refined students' movement precision.

Conversely, mental balance showed much improvement also after the intervention. This outcome emphasizes the emotional and cognitive gains from motor learning. Developing mental resilience calls for attention, concentration, and the ability to control emotional reactions under pressure—all of which are required of structured movement tasks. The kids most certainly developed better control of their tension, concentration on their work, and composure under physical demands. This result is consistent with earlier studies demonstrating that physical activity—especially when combined with coordination activities—can improve cognitive performance, lower anxiety, and raise mood.

Furthermore, the simultaneous enhancement in physical and cerebral spheres highlights the integrated character of motor learning. It is a whole learning experience that links movement with brain processes, not only a physical one. In the framework of physical education, where children are expected to develop not only physical competencies but also emotional and cognitive skills supporting lifetime health and well-being, this whole development is crucial. These results also imply pragmatic

consequences for the design of physical education courses. Including motor learning ideas in regular training sessions or academic courses can yield essential advantages beyond only physical fitness. Balance games, dual-task exercises, and sport-specific skill learning, including decision-making, are among the activities educators and coaches are urged to create challenging both motor and cognitive systems.

This research validates motor learning's favorable contribution to enabling balanced physical and psychological growth. Future research may examine the long-term impacts of such programs, contrast several kinds of motor learning interventions, or study their effects on other groups, such as younger pupils or athletes in high-performance environments.

## CONCLUSION

This study results show that among fourth-semester Physical Education students, motor learning is essential for improving both physical and mental balance. Strong statistical data ( $p < 0.05$ ) supports the notable increases in the post-test scores, which confirm that well-organized and well-designed motor learning programs can efficiently build students' neuromuscular coordination and emotional control. The results show that while mental balance is improved by increased attention, confidence, and stress management derived from engaging movement experiences, physical balance benefits are tightly tied to repetitive motor activities and sensorimotor training. This double advantage helps to include motor learning strategies into the physical education program, therefore enhancing not only physical fitness but also mental stability and psychological readiness.

In the end, motor learning is an educational instrument that helps children grow physically, intellectually, and emotionally. Future studies are invited to investigate the long-term viability of these advantages and evaluate the efficiency of several forms of motor learning models in various educational and sporting environments.
